Resumo – A VEGETAÇÃO COSTEIRA DO SECTOR DIVISÓRIO PORTUGUÊS: COMUNIDADES DAS DUNAS, ARRIBAS E MATOS. O Sector Divisório Português é uma unidade biogeográfica original, que está incluída na Província Gaditano-Onubo-Algarviense da Região Mediterrâника. Na sua área costeira reconhecem-se quatro Superdistritos distintos: Olissiponense, Sintrano, Costeiro Português e Berlenguense. O Costeiro Português é o maior dos territórios, cuja flora possui características mediterrânicas e atlânticas devido à sua paleo-história e às vias migratórias das plantas entre as Regiões Mediterrâника e Eurossiberiana. Devido a estas múltiplas influências, este território possui uma grande biodiversidade e tem uma riqueza original de táxones e sintáxones, sendo importante que lhe seja atribuído um estatuto de conservação. No presente trabalho, fazemos a caracterização breve de 27 associações de dunas e arribas que ocorrem neste Sector. As comunidades e os táxones que são endémicos ou possuem estatuto de conservação são citados. Também se propõem quatro novos sintáxones.

Palavras-chave: Biogeografia, Fitossociologia, Vegetação, Flora, Sector Divisório Português.

Abstract – The Portuguese Divisory Sector is an original biogeographical unit within the Gaditano-Onubo-Algarvish Province of the Mediterranean chorological region. There are four superdistricts along its coastal area: «Olissiponense», «Sintrano», «Costeiro Português» (Portuguese Coastal) and «Berlenguense». The Portuguese Coastal superdistrict has not been sufficiently studied; it is the largest and its transitional biogeographical character lies between those of the Mediterranean and Eurosiberian regions due to its paleo-ecological history and joint position in relation to Atlantic and Mediterranean floristic migratory pathways. Due to these multiple influences a wealth of original taxa and syntaxa are found there which make large areas of the region suited for biodiversity conservation. In this work we characterise briefly 27 plant associations of dunes and sea-cliffs. Endemic or protect *taxa* and communities are cited. We also propose four new syntaxes.

Key words: Biogeography, Phytosociology, vegetation, flora, Portuguese Divisory Sector

I. INTRODUCTION

In terms of phytogeographical typology and following COSTA *et al.* (1998), the coastal area studied is included in «Divisório Português» (Portuguese Divisory) Sector (Gaditano-Onubo-Algarvish Province Mediterranean-Ibero-Atlantic Superprovince, Western Mediterranean Subregion, Mediterranean Region). It is formed by four Superdistricts: «Olissiponense» (Lisbon area), «Sintrano» (Sintra range), «Berlenguense» (Berlengas islands) and «Costeiro Português» (Portuguese Coastal, fig. 1). These units are characterized by coastal landscape systems (*geosigmetum*) including both dunes, cliffs, and low-shrub communities under more or less direct influence of maritime winds. It ranges approximately from Lisbon to Aveiro where it comes into contact with the Cantabro-Atlantic Province (Eurosiberian Region). Both climatic influence and paleo-historical nature of this unit are peculiar due to its transitional character and interface position in the main littoral plant migratory pathways (IZCO, 1983, 1992, 1993). In the «Olissiponense» Superdistrict the limestone cliffs are predominant, dunes can also be included in thermomediterranean thermotype and in dry ombrotype (COSTA *et al.*, 1993). In the «Sintrano» Superdistrict the granitic cliffs are dominant, in meso-Mediterranean thermotype and the sub-humid ombrotype. In the Portuguese Coastal Superdistrict between Sintra and Nazaré the lime or sandstone cliffs are sometimes interrupted by small beaches; north of Nazaré the coast is dominated by more or less altered dune systems, with a few calcareous outcrops (e.g. Cape Mondego). Most of the area belongs to the thermo-Mediterranean thermotype, except for a small area (Pinhal de Leiria, Mira and Quiaios coast). The former are of mesomediterranean type. The ombroclimate is of the subhumid ombrotype. Nevertheless, as expected in coastal areas, some physiological drought dominates the area due to somewhat persistent winds during winter and fall. The «Berlenguense» Superdistrict is formed by small granitic islands. There has been a strong human influence on this area

since the Middle Ages. Extensive plantations of maritime-pine (*Pinus pinaster*), dating mostly from the 19th century, also shape the landscape from Nazaré to Aveiro. These pine stands were planted for timber and to prevent the advance of dunes inland. Previous vegetation studies were those of BRAUN-BANQUET *et al.* (1964, 1972). The aim of this work is to extend some of the knowledge mostly on cliff and dune vegetation of the Portuguese Divisory Sector.

II. VEGETATION

1. Dunes and low-scrub communities

South of Carvoeiro Cape the first dune community occurring close to the sea is the *Salsolo kali-Cakiletum maritimae*. This Mediterranean therophytic vegetation occurs on a small strip of organic debris carried by tides. Dominant taxa are: *Cakile maritima* ssp. *maritima*, *Euphorbia peplis* and *Salsola kali*. It is often destroyed by bathers. *Honkenya peploides* is a scarce but more frequent north of Peniche. This species with *Cakile maritima* ssp. *integrifolia* forms the Atlantic community *Honckenyo-Euphorbietum peplis*.

In the second strip of mobile sand, embryonic dunes, a hemicriptophytic community appears: *Euphorbio paraliae-Agropyretum junceiformis* (syn. = *Eryngio-Honkenietum peploidis* J. & G. Br.-Bl., Rozeira & P. Silva 1972 = *Agropyro junceiformis-Otanthesetum maritimi agropyro-crucianellietosum* J. & G. Br.-Bl., Rozeira & P. Silva 1972). The dominant taxa are: *Elymus farctus* ssp. *boreali-atlanticus*, *Euphorbia paralias*, *Eryngium maritimum*, *Calystegia soldanella* and *Pancratium maritimum* (table I). The subassociation *otanthesetum maritimae*, which is abundant, is a result of the destruction of the *Ammophila arenaria* ssp. *australis* communities by the sea storms during winter.

The mobile dune crests are occupied by two associations: *Otanthon-Ammophiletum australis* (syn.= *Agropyro-Otanthesetum maritimi ammophiletosum arenariae* J. & G. Br.-Bl., Rozeira & P. Silva 1972) and *Loto cretic-Ammophiletum australis*. The first community ranges from the coast of the Basque country to Peniche (approximately the midpoint of our study area). Chamaephytic and hemicriptophytic taxa such as *Ammophila arenaria* ssp. *australis*, *Otanthus maritimus*, *Eryngium maritimum*, *Medicago marina*, *Calystegia soldanella* are frequent. The subassociation *crucianellietosum maritimae* take place in the area where the sand begins to settle (table II). The *Otanthon-Ammophiletum* sometimes is found far from the sea (up to 3 Km inland) due to strong winds (Leiria pinewoods). The second community (*Loto-Ammophiletum*) follows the west-Mediterranean coasts both in Morocco and the Iberian Peninsula (from Tarifa to Praia da Areia Branca). It differs from the former *Ammophila* community mostly by the strong abundance of *Lotus creticus* (table III). We propose the new subassociation *armerietosum welwitschii* specific

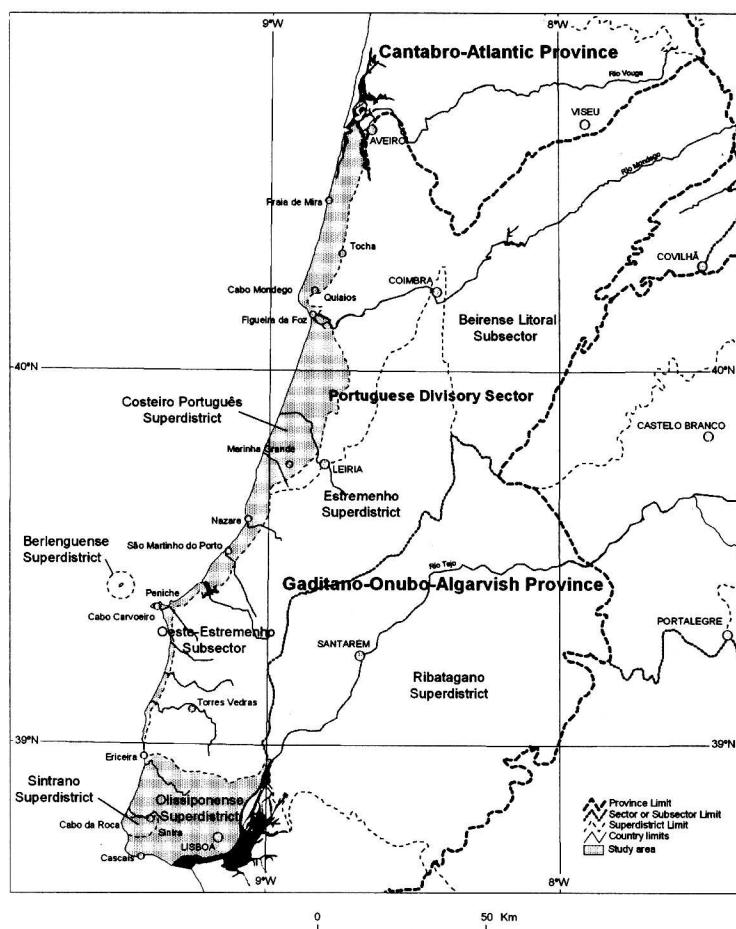

Fig.1 – Biogeographic map of the study area

Fig.1 – Mapa biogeográfico da área de estudo

of Portuguese Divisory Sector, where the contact with moving sands and stable sands occurs and *Armeria welwitschii* ssp. *welwitschii*, *Artemisia crithmifolia*, *Helichrysum picardi*, *Ononis natrix* ssp. *ramosissima*, *Crucianella maritima* are the differential species (*syntypus* releve 7, table III).

The grey dunes, where chamaephytes dominate and the sands are fixed, two associations are present. The first is endemic to the study area *Armerio welwitschii-Crucianellietum maritimae*. Its floristic composition includes: *Crucianella maritima*, *Helichrysum picardi*, *Armeria welwitschii* ssp. *welwitschii*, *Artemisia crithmifolia*, *Pancratium maritimum*, *Lotus creticus*, *Ononis natrix* ssp. *ramosissima*, *Malcolmia littorea*, *Carpobrotus edulis*, *Sedum sediforme*, *Aethorhiza*

bulbosa, *Scrophularia frutescens*, *Euphorbia portlandica*, *Iberis procumbens* ssp. *procumbens*, *Verbascum litigiosum*, *Cyperus capitatus*, *Seseli tortuosum*, *Linaria caesia* ssp. *decumbens*, *Vulpia alopecurus*, *Corynephorus canescens* var. *maritimus* and *Calendula suffruticosa* ssp. *algarbiense* (table IV). The community ranges from Cascais to Quiaios where it is replaced by the second community: the Atlantic association *Scrophulario-Vulpietum alopecuris* (syn. *Iberidetum procumbentis* Bellot 1966, pp.). It differs from the former by a great abundance of *Vulpia alopecurus*, *Seseli tortuosum*, *Herniaria ciliolata* ssp. *robusta*, *Leontodon arenarius* and the absence of *Armeria welwitschii*, *Lotus creticus* and *Herniaria maritima* (table V). In the study area the characteristic species *Jasione lusitanica* and *Coincyia johnstonii* are absent. It is endemic of the NW of the Iberian Peninsula. During springtime, the clearings of both these low-shrub formations are filled with an endemic therophitic community: *Violo henriquesii-Silenetum littoreae* (*Silene littorea*, *Senecio gallicus*, *Polycarpon alsinifolium*, *Erodium aethiopicum* ssp. *pilosum*, *Medicago littoralis*, *Pseudor-laya minuscula*, etc., table VI). It is also endemic and ranges from Cascais to Galiza (NW Spain).

The mature vegetation of stable dunes is the thermomediterranean *Juniperus turbinata* community: *Osyrio quadripartitiae-Juniperetum turbinatae*. It is an endemic syntaxon of the sand dunes from Cadiz to Mondego Cape (Gaditano-Onubo-Algarvish Province). It appears in fossil dunes in sea-cliffs. Its composition includes: *Juniperus turbinata* ssp. *turbinata*, *Rubia peregrina* var. *longifolia*, *Asparagus aphyllus*, *Daphne gnidium*, *Pistacia lentiscus*, *Phillyrea angustifolia*, *Smilax aspera* var. *mauritanica*, *Corema album*, *Antirrhinum majus* ssp. *cirrigerum*, etc. (table VII). The fringe and the first stage of degradation is *Rubio longifoliae-Coremetum albi* association (table VIII). It follows the geographical distribution of the *Juniperus* community and reaches northern sites near Aveiro. Its floristic character comes from the combination of *Corema album*, *Rubia peregrina* var. *longifolia* and *Antirrhinum majus* ssp. *cirrigerum*. This community is absent in Olissiponense Superdistrict.

The nanophanerophytic *Stauracantho genistoidis-Coremvetum albi* (table IX) is a low-shrub community endemic to the Portuguese Coastal Superdistrict. It's very abundant under the pine stands and is probably the mature vegetation of the interior dunes, despite sometimes being in contact with the *Juniperus* community. The community is dominated by *Stauracanthus genistoides*, *Corema album*, *Ulex europaeus* ssp. *latebracteatus*, *Helichrysum picardi* var. *virescens*, *Halimium calycinum*, etc. It is a transitional community between *Cisto-Lavanduletea* and *Calluno-Ulicetea*. This association results from the destruction of the strawberrytree community *Myrica fayae-Arbutetum unedonis*, which is the climax in the sandy soils of Portuguese Coastal Superdistrict. *Arbutus unedo*, *Myrica faya*, *Erica arborea*, *Cytisus grandiflorus* are the more common species (CAPELO et al. 1998).

In general, wherever the dune communities have inputs of nitrogen compounds from organic matter (human disturbance) the *Chamaemelo mixti-Vulpietum alopecuoris* association appears. Frequent species are: *Vulpia alope-*

curus, *Chamaemelum mixtum*, *Centranthus calcitrapa*, *Bromus diandrus*, *Brassica barrelieri* ssp. *oxyrrhina*, *Arcotheca calendula*, *Lagurus ovatus*, *Reichardia gaditana*, *Silene colorata*, etc. (syntypus releve 11, table X). This association can be found on semi-nitrophilous sandy soils from south Aveiro to southwest Spain (RIVAS-MARTÍNEZ *et al.*, 1980, COSTA *et al.* 1997, LOUSÁ *et al.*, 1999). The nitrophilous *Anacyclo radiati-Hordeetum leporini arcothecetosum calendulae* is also found near roads in sandy soils. *Hordeum murinum* ssp. *leporinum*, *Anacyclus radiatus*, *Arcotheca calendula* are the dominant species in this SW-Iberian formation.

2. Sea-cliffs

In the limestone sea-cliffs of the Sector we found the most original flora and vegetation. In the late fall the strong salt-rich winds result in physiological dryness although the annual rainfall is high. In the most exposed sites three associations belonging to the Mediterranean alliance *Crithmo-Daucion halophili* (*Crithmo-Staticetea maritimae*) are found. The southernmost one is found from Peniche to Lisbon, except for the granites of Roca Cape, and is named *Limonietum multifloro-virgati*. Besides *Limonium virgatum* (= *L. oleifolium*) and *Limonium multiflorum* also common are *Dactylis marina*, *Crithmum maritimum*, *Plantago coronopus* ssp. *occidentalis*, *Daucus halophilus*, *Spergularia australis*, *Armeria welwitschii* ssp. *cinerea*, *Frankenia laevis*, *Inula crithmoides*, *Limonium ferulaceum* (COSTA *et al.*, 1998). Between the capes Carvoeiro (Peniche) and Mondego a community with a similar composition is found, but *L. multiflorum* and *L. virgatum* are absent and replaced by *Limonium plurisquamatum* and *Limonium ovalifolium*. This association is the *Dactylo marinae-Limonietum plurisquamati*. Both associations are found mostly on limestone and rarely on sandstone. The *Diantho cintrani-Daucetum halophili* is endemic among the granitic cliffs of Sintrano Superdistrict. *Daucus halophilus*, *Dactylis marina*, *Crithmum maritimum*, *Limonium virgatum*, *Dianthus cintranus* ssp. *cintranus*, *Armeria pseudarmeria*, *Plantago coronopus* ssp. *occidentalis* are the most frequent species (COSTA *et al.*, 1998). The *Spergulario rupicolae-Armerietum berlengensis*, is also endemic and occurs on the granitic cliffs of the Berlenguense Superdistrict. It is formed by *Armeria berlengensis*, *Crithmum maritimum*, *Dactylis marina*, *Spergularia rupicola*, *Plantago coronopus* ssp. *occidentalis*, *Silene uniflora*, *Angelica pachycarpa*, etc. (COSTA *et al.*, 1998). This community belongs to the Atlantic alliance *Crithmion maritimae*. In spring-time, an aerohalophilic and nitrophilous annual community resulting from the destruction of the *Limonium* communities is found: *Parapholido incurvae-Catapodietum marini* (*Saginetea maritimae*), where *Parapholis incurva*, *Catapodium marinum*, *Leontodon taraxacoides* are frequent (COSTA *et al.*, 1998). This community is found in the SW of the Iberian Peninsula and Balearic islands

(RIVAS-MARTÍNEZ *et al.*, 1990). But in the Berlenguense Superdistrict we can see *Cochlearia danica* and *Sagina maritima* that form the Atlantic association *Sagino maritimae-Cochlearietum danicae* (COSTA *et al.*, 1998). In the resting and feeding places of sea birds a community of halonitrophilous nanophanerophytes can be found. This vegetation belongs to the *Pegano-Salsoletea* vegetation class. *Atriplex halimus*, *Suaeda vera*, *Frankenia laevis*, *Beta vulgaris* ssp. *maritima*, *Imula crithmoides* are abundant – *Scrophulario sublyratae-Suaedetum verae* (COSTA *et al.*, 2000).

The climax vegetation (permanent community) of sea-cliffs is the juniper community *Querco cocciferae-Juniperetum turbinatae*. Although the two name-giving taxa are dominant in the community, *Asparagus aphyllus*, *Olea europaea* var. *sylvestris*, *Rubia peregrina* var. *longifolia*, *Rhamnus alaternus*, etc. can also be found (table XI). It is an endemic community of Portugal and can be found from the Mondego cape to the Algarve (COSTA *et al.*, 1994). The theoretical climatic climax is not achieved on the sea cliffs due to the drying effect of strong winds despite the high annual rainfall in these environments.

The *Cisto salvifolii-Ulicetum humilis lavanduletosum luiseri* is another endemic syntaxon of the Portuguese Coastal Superdistrict (HONRADO *et al.*, 1999). It is an Atlantic community and can be found in the Foz do Arelho sea cliffs and it is formed by *Ulex europaeus* ssp. *latebracteatus* f. *humilis*, *Cistus salvifolius*, *Erica umbellata*, *Daphne gnidium* var. *maritima*, *Genista triacanthos*, *Brachypodium rupestre*, *Calluna vulgaris*, *Pseudarrhenatherum longifolium*, *Carlina corymbosa* var. *major*, *Dactylis marina*, *Asparagus aphyllus*, *Lavandula luisieri*, *Cistus ladanifer*, *Rubia peregrina* var. *longifolia*, *Phillyrea angustifolia* and others.

In «Sintrano» and the southmost Portuguese Coastal Superdistrict, on granitic soils and fossil and consolidated dunes, we can see the new community *Daphno maritimi-Ulicetum congesti*; it is dominated by the endemic *Ulex jussiaei* ssp. *congestus* with *Daphne gnidium* var. *maritima*, *Carlina corymbosa* var. *major*, *Armeria pseudarmeria*, *Daucus halophilus*, *Dactylis marina*, *Euphorbia portlandica*, *Calluna vulgaris*, etc. (syntypes relieve 2, table XII). It also forms a mosaic with the *Querco cocciferae-Juniperetum turbinatae*. It is the southernmost association of the Atlantic alliance of sea-cliffs: *Dactylido maritimae-Ulicion maritimi*. It is endemic to the study area. We confirm this association in this work.

South of Nazaré, on limestone soils, the degradation of the juniper community results in a *Ulex densus* dominated low scrub. Other common species are: *Salvia sclareoides*, *Eryngium dilatatum*, *Anthyllis vulneraria* ssp. *maura*, *Plantago serraria* var. *hispanica*: *Salvio sclareoidis-Ulicetum densi ulicetosum densi* (table XIII). It is an endemic community of the Portuguese Divisory Sector. *Daphne gnidium* var. *maritima*, *Dactylis marina*, *Daucus halophilus*, *Carlina corymbosa* var. *major*, *Ononis natrix* ssp. *ramosissima*, *Calendula suffruticosa* ssp. *algarbiensis*, *Helichrysum decumbens* define a coastal variant of this association (variant of *Daphne maritima*) in relation to the typical community of

the Portuguese Coastal Superdistrict. It forms mosaic with the meadows of *Brachypodium phoenicoides* (*Phlomido lychnitidis-Brachypodietum phoenicoidis*) which are a wild-orchid rich habitat.

Other cliff communities are: reed communities of *Arundo donax* (*Arundini donacis-Convolvuletum sepium*) and *Tamarix africana* communities of semi-natural characteristics since these are promoted by cultivation for purposes of protection against sea-winds.

III. FLORA

The flora of the Portuguese coastal Superdistrict is mostly of the Mediterranean floristic element but includes several Atlantic groups of taxa since this area doesn't have any natural climatic or geographical barriers between the two influences. Typically Mediterranean taxa area found, such as: *Juniperus turbinata*, *Quercus lusitanica*, *Quercus coccifera*, *Cakile maritima* ssp. *maritima*, *Brassica barrelieri* ssp. *oxyrrhina*, *Lotus creticus*, *Stauracanthus genistoides*, *Daucus halophilus*, *Limonium virgatum*, *Corema album*, *Antirrhinum majus* ssp. *cirrhigerum*, *Anacyclus radiatus*, *Artemisia crithmifolia*, *Calendula suffruticosa* ssp. *algarbiensis*, *Helichrysum decumbens*, *Helichrysum picardi*, *Asparagus aphyllus*, etc., and Atlantic: *Salix arenaria*, *Honkenya peploides*, *Herniaria ciliolata* ssp. *robusta*, *Cakile maritima* ssp. *integrifolia*, *Cochlearia danica*, *Malcolmia ramosissima*, *Matthiola sinuata*, *Ulex europaeus* ssp. *latebracteatus*, *Hypericum elodes*, *Ange-lica plachyparca*, *Triglochin maritima*, *Elymus pycnanthus*, *Puccinellia maritima*, *Carex trinervis*, *Schoenoplectus supinus* etc.

Taxa endemic of the study area: *Dianthus cintranus* ssp. *cintranus*, *Herniaria berlengiana*, *Ulex jussiaei* var. *jussiaei* and var. *congestus*, *Armeria pseudarmeria*, *A. welwitschii* ssp. *welwitschii* and ssp. *cinerea*, *A. berlengensis*, *Limonium multiflorum*, *L. laxiusculum*, *L. plurisquamatum*, *Omphalodes kuzinskyanae*. Taxa endemic of Portugal: *Herniaria maritima*, *Ionopsisidium acaule* (Bern Convention species), *Iberis procumbens* ssp. *microcarpa*, *Silene longicilia*, *Ulex densus*, *Euphorbia transtagana*, *Myosotis lusitanica*, *Antirrhinum majus* ssp. *linkianum*, *Verbascum litigiosum*, *Scrophularia sublyrata*, *Cirsium welwitschii*, *Allium pruinatum*. Taxa endemic of the Iberian Peninsula: *Silene scabriflora*, *Iberis procumbens* ssp. *procumbens*, *I. linifolia* ssp. *welwitschii*, *Cytisus striatus*, *C. grandiflorus*, *Stauracanthus genistoides*, *Lotus subbiflorus* ssp. *castellanus*, *Euphorbia uliginosa*, *Cistus psilosepalus*, *Angelica pachycarpa*, *Peuce-danum lancifolium*, *Corema album*, *Centaureum microcalyx*, *Anchusa calcarea*, *Myosotis persoonii*, *Callitricha lusitanica*, *Calamintha baetica*, *Thymus villosus*, *Lavandula luisieri*, *L. pedunculata* ssp. *lusitanica*, *Salvia sclareoides*, *Gratiola linifolia*, *Linaria caesia* ssp. *decumbens*, *Odontites tenuifolia*, *Pulicaria paludosa*, *Artemisia crithmifolia*, *Cirsium filipendulum* ssp. *filipendulum*, *Serratula monardii*, *Avenula sulcata* ssp. *occidentalis*, *Vulpia fontquerana*. Taxa

e n d e m i c
of Europe: *Pilularia globulifera*, *Herniaria ciliolata* ssp. *robusta*, *Cochlearia danica*, *Hypericum elodes*, *Carum verticillatum*, *Pseudorlaya minuscula*, *Centaurium chloodes*, *Myosotis ramosissima* ssp. *globularis*, *M. balbisiana*, *Callitricha truncata* ssp. *occidentalis*, *C. brutia*, *Teucrium scorodonia* ssp. *scorodonia*, *Verbascum thapsus* ssp. *crassifolium*, *Verbascum virgatum*, *Anarrhinum bellidifolium*, *Linaria spartea*, *Wahlenbergia hederacea*, *Taraxacum adamii*, *Elymus pycnanthus*, *Carex arenaria*, *Carex trinervis*.

Schoenoplectus supinus (L.) Palla was observed for the first time in Portugal (Vela lagoon). In this study area, several exotic taxa are frequent, such as: *Acacia melanoxylon*, *A. longifolia*, *Carpobrotus edulis*, *Hydrocotyle bonariensis*, *Cotula coronopifolia*, *Myriophyllum aquaticum*, *Oenothera stricta*, *Elodea canadensis*. *Acacia* spp., *Carpobrotus edulis* and *Myriophyllum aquaticum* are invaders in the area and cause problems of vegetation conservation.
